(54) Title: MANIPULATION OF *MLO* GENES TO ENHANCE DISEASE RESISTANCE IN PLANTS

Maize *MLO* Resistance Gene Homologues

(57) Abstract

Compositions and methods for enhancing disease resistance in plants are provided. The method involves modulating the activity of *Mlo* sequences in the plant. Particular *Mlo* sequences are provided that can be manipulated to enhance pathogen resistance in modified plants. Transformed plants, plant cells, tissues, and seed are also provided having enhanced disease resistance.

MANIPULATION OF *MLO* GENES
TO ENHANCE DISEASE RESISTANCE IN PLANTS

5

FIELD OF THE INVENTION

The invention relates to the genetic manipulation of plants, particularly to transforming plants with genes that enhance disease resistance.

BACKGROUND OF THE INVENTION

10

Disease in plants is caused by biotic and abiotic causes. Biotic causes include fungi, viruses, bacteria, and nematodes. Of these, fungi are the most frequent causative agent of disease on plants. Abiotic causes of disease in plants include extremes of temperature, water, oxygen, soil pH, plus nutrient-element deficiencies and imbalances, excess heavy metals, and air pollution.

15

A host of cellular processes enables plants to defend themselves from disease caused by pathogenic agents. These processes apparently form an integrated set of resistance mechanisms that is activated by initial infection and then limits further spread of the invading pathogenic microorganism. This limitation of the pathogen intruder is frequently accomplished by localized containment of the intruder following a coordinated complex defense response.

20

Subsequent to recognition of a potentially pathogenic microbe, plants can activate an array of biochemical responses. Generally, the plant responds by inducing several local responses in the cells immediately surrounding the infection site. The most common resistance response observed in both nonhost and race-specific interactions is termed the "hypersensitive response" (HR). In the hypersensitive response, cells contacted by the pathogen, and often neighboring cells, rapidly collapse and dry in a necrotic fleck. Other responses include the deposition of callose, the physical thickening of cell walls by lignification, and the synthesis of various antibiotic small molecules and proteins. Genetic factors in both the host and the pathogen determine the specificity of these local responses, which can be very effective in limiting the spread of infection.

25
30

The hypersensitive response in many plant-pathogen interactions is specified by and dependent on the presence of two complementary genes, one from the host and one from the pathogen. These complementary genes are the resistance (*R*) gene in the plant and a corresponding avirulence (*avr*) gene in the pathogen. The interaction of the genes is associated with the rapid, localized cell death of the hypersensitive response. *R* genes that respond to specific bacterial, fungal, or viral pathogens, have been isolated from a variety of plant species and several appear to encode cytoplasmic proteins.

The resistance gene in the plant and the avirulence gene in the pathogen often conform to a gene-for-gene relationship. That is, resistance to a pathogen is only observed when the pathogen carries a specific avirulence gene and the plant carries a corresponding or complementing resistance gene. Because *avr-R* gene-for-gene relationships are observed in many plant-pathogen systems and are accompanied by a characteristic set of defense responses, a common molecular mechanism underlying *avr-R* gene mediated resistance has been postulated. A simple model which has been proposed is that pathogen *avr* genes directly or indirectly generate a specific molecular signal (ligand) that is recognized by cognate receptors encoded by plant *R* genes.

Both plant resistance genes and corresponding pathogen avirulence genes have been cloned. The plant kingdom contains thousands of *R* genes with specific specificities for viral, bacterial, fungal, or nematode pathogens. Although there are differences in the defense responses induced during different plant-pathogen interactions, some common themes are apparent among *R* gene-mediated defenses. The function of a given *R* gene is dependent on the genotype of the pathogen. Plant pathogens produce a diversity of potential signals, and in a fashion analogous to the production of antigens by mammalian pathogens, some of these signals are detectable by some plants.

The avirulence gene causes the pathogen to produce a signal that triggers a strong defense response in a plant with the appropriate *R* gene. However, expressing an avirulence gene does not stop the pathogen from being virulent on hosts that lack the corresponding *R* gene. A single plant can have many *R* genes, and a pathogen can have many *avr* genes.

Monogenic resistance mediated by recessive (*mlo*) alleles of the *Mlo* locus is different. It differs from race-specific incompatibility to single pathogen strains in that it is believed to confer a broad spectrum resistance to almost all known isolates of the fungal pathogen, and the resistance is
5 apparently durable in the field despite extensive cultivation. Further, *mlo* resistance alleles have been obtained by mutagen treatment of susceptible wild-type *Mlo* varieties. These *mlo* plants exhibit a spontaneous leaf cell death phenotype under pathogen-free or even axenic conditions.

As noted, among the causative agents of infectious disease of crop
10 plants, the phytopathogenic fungi play the dominant role. Phytopathogenic fungi cause devastating epidemics, as well as causing significant annual crop yield losses. All of the approximately 300,000 species of flowering plants are attacked by pathogenic fungi. However, a single plant species can be host to only a few fungal species, and similarly, most fungi usually have a limited host
15 range.

Plant disease outbreaks have resulted in catastrophic crop failures that have triggered famines and caused major social change. Generally, the best strategy for plant disease control is to use resistant cultivars selected or developed by plant breeders for this purpose. However, the potential for serious
20 crop disease epidemics persists today, as evidenced by outbreaks of the Victoria blight of oats and southern corn leaf blight.

Accordingly, molecular methods are needed to supplement traditional breeding methods to protect plants from pathogen attack. Particularly, methods are needed for broad spectrum resistance to pathogens.
25

SUMMARY OF THE INVENTION

Compositions and methods for creating or enhancing resistance to plant pests are provided. The method provides control of pathogens by modulating the expression of *Mlo* genes. Novel *Mlo* sequences are provided from maize.

- 5 Such sequences can be utilized to modulate the expression of *Mlo* genes in plants, particularly maize, to enhance resistance to pathogens. Generally, such modulation will result in decreased or increased expression of native *Mlo* genes, preferably decreased expression. Such decreased expression can be effected by mutagenesis or expression of modified or antisense *Mlo* sequences described
10 herein.

- It is recognized that a variety of promoters will be useful in the invention the choice of which will depend in part upon the desired level of expression of the modified sequences in the plant or alternatively, in the plant organ. It is recognized that the levels of expression can be controlled to induce
15 broad spectrum resistance resulting in levels of immunity in the plant or to induce cell death.

- The methods of the invention find use in controlling plant pests, including fungal pathogens, viruses, nematodes, insects, and the like. Transformed plants and seeds, as well as methods for making such plants and
20 seeds are additionally provided.

BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 provides a sequence alignment for the maize *Mlo* homologues with the barley *Mlo* sequence. The barley sequence is designated as Hv*Mlo*1.

- 25 Figure 2 groups the *Mlo* sequences based on relatedness as well as the plant tissue from which it was isolated.

Figure 3 schematically illustrates a plasmid vector comprising the *ZmMlo*1 antisense construct operably linked to the ubiquitin promoter.

DETAILED DESCRIPTION OF THE INVENTION

Compositions of the invention include eight mutation-induced recessive alleles of maize set forth in SEQ ID NOS: 1, 3, 5, 7, 9, 11, 13 and 15. The maize sequences exhibit homology to the *Mlo* barley sequence (SEQ ID NO: 5 17). See, Büschges *et al.* (1997) 88:695-705 and Tables 1 and 2. The isolated maize *Mlo* genes are involved in enhancing resistance to plant pests. In particular, the present invention provides for isolated nucleic acid molecules comprising nucleotide sequences encoding the amino acid sequences shown in SEQ ID NOS: 2, 4, 6, 8, 10, 12, 14, 16, or the nucleotide sequences encoding 10 the DNA sequences deposited in a bacterial host with the American Type Culture Collection and assigned the Accession Nos. 98725, 98726, 98727, 98728, 98729 (SEQ ID NOS: 3, 5, 9, 11, 13 respectively). Further provided are polypeptides having an amino acid sequence encoded by a nucleic acid molecule described herein, for example those set forth in SEQ ID NOS: 1, 5, 3, 15 7, 9, 11, 13, and 15, those deposited with the American Type Culture Collection and assigned Accession Nos. 98725, 98726, 98727, 98728, 98729 (SEQ ID NOS: 3, 5, 9, 11, 13 respectively), and fragments and variants thereof.

Plasmids containing the nucleotide sequences of the invention were deposited with American Type Culture Collection, Manassas, Virginia, and 20 assigned Accession Nos. 98725, 98726, 98727, 98728, 98729 (SEQ ID NOS: 3, 5, 9, 11, 13 respectively). These deposits will be maintained under the terms of the Budapest Treaty on the International Recognition of the Deposit of Microorganisms for the Purposes of Patent Procedure. These deposits were made merely as a convenience for those of skill in the art and are not an 25 admission that a deposit is required under 35 U.S.C. §112.

The invention encompasses isolated or substantially purified nucleic acid or protein compositions. An "isolated" or "purified" nucleic acid molecule or protein, or biologically active portion thereof, is substantially free of other cellular material, or culture medium when produced by recombinant techniques, 30 or substantially free of chemical precursors or other chemicals when chemically synthesized. Preferably, an "isolated" nucleic acid is free of sequences (preferably protein encoding sequences) that naturally flank the nucleic acid (i.e., sequences located at the 5' and 3' ends of the nucleic acid) in the genomic

DNA of the organism from which the nucleic acid is derived. For example, in various embodiments, the isolated nucleic acid molecule can contain less than about 5 kb, 4 kb, 3 kb, 2 kb, 1 kb, 0.5 kb, or 0.1 kb of nucleotide sequences that naturally flank the nucleic acid molecule in genomic DNA of the cell from which the nucleic acid is derived. A protein that is substantially free of cellular material includes preparations of protein having less than about 30%, 20%, 10%, 5%, (by dry weight) of contaminating protein. When the protein of the invention or biologically active portion thereof is recombinantly produced, preferably culture medium represents less than about 30%, 20%, 10%, or 5% (by dry weight) of chemical precursors or non-protein-of-interest chemicals.

Fragments and variants of the disclosed nucleotide sequences and proteins encoded thereby are also encompassed by the present invention. By "fragment" is intended a portion of the nucleotide sequence or a portion of the amino acid sequence and hence protein encoded thereby. Fragments of a nucleotide sequence may encode protein fragments that retain the biological activity of the native protein and hence their altered expression enhances resistance to pathogens. Alternatively, fragments of a nucleotide sequence that are useful as hybridization probes generally do not encode protein fragments retaining biological activity. Thus, fragments of a nucleotide sequence may range from at least about 20 nucleotides, about 50 nucleotides, about 100 nucleotides, and up to the full-length nucleotide sequence encoding the proteins of the invention.

A fragment of a *Mlo* nucleotide sequence that encodes a biologically active portion of a *Mlo* protein of the invention will encode at least 15, 20, 25, 30, 40, 50, 75, 100, 200, 250, 300, 350, 400, 450, 500, or 550 contiguous amino acids, or up to the total number of amino acids present in a full-length MLO protein of the invention. (For example, 509, 499, and 492, amino acids for SEQ ID NOS: 6, 12, and 14 respectively.) Fragments of a *Mlo* nucleotide sequence that are useful as hybridization probes for PCR primers generally need not encode a biologically active portion of a MLO protein.

Thus, a fragment of a *Mlo* nucleotide sequence may encode a biologically active portion of a MLO protein, or it may be a fragment that can be used as a hybridization probe or PCR primer using methods disclosed below.

A biologically active portion of a MLO protein can be prepared by isolating a portion of one of the *Mlo* nucleotide sequences of the invention, expressing the encoded portion of the MLO protein (e.g., by recombinant expression *in vitro*), and assessing the activity of the encoded portion of the MLO protein. Nucleic acid molecules that are fragments of a *Mlo* nucleotide sequence comprise at least 16, 20, 50, 75, 100, 150, 200, 250, 300, 350, 400, 450, 500, 550, 600, 650, 700, 800, 900, 1,000, 1,100, 1,200, 1,300, 1,400, 1,500, 1,600, 1,700, 1,800, 1,900, and 2,000 nucleotides, or up to the number of nucleotides present in a full-length *Mlo* nucleotide sequence disclosed herein.

By "variants" is intended substantially similar sequences. For nucleotide sequences, conservative variants include those sequences that, because of the degeneracy of the genetic code, encode the amino acid sequence of one of the MLO polypeptides of the invention. Naturally occurring allelic variants such as these can be identified with the use of well-known molecular biology techniques, as, for example, with polymerase chain reaction (PCR) and hybridization techniques as outlined below. Variant nucleotide sequences also include synthetically derived nucleotide sequences, such as those generated, for example, by using site-directed mutagenesis but which still encode a MLO protein of the invention. Generally, nucleotide sequence variants of the invention will have at least 40%, 50%, 60%, 70%, generally, 80%, preferably 85%, 90%, up to 95%, 98% sequence identity to its respective native nucleotide sequence.

By "variant" protein is intended a protein derived from the native protein by deletion (so-called truncation) or addition of one or more amino acids to the N-terminal and/or C-terminal end of the native protein; deletion or addition of one or more amino acids at one or more sites in the native protein; or substitution of one or more amino acids at one or more sites in the native protein. Such variants may result from, for example, genetic polymorphism or from human manipulation.

The proteins of the invention may be altered in various ways including amino acid substitutions, deletions, truncations, and insertions. Methods for such manipulations are generally known in the art. For example, amino acid sequence variants of the *Mlo* proteins can be prepared by mutations in the DNA.

Methods for mutagenesis and nucleotide sequence alterations are well known in the art. See, for example, Kunkel (1985) *Proc. Natl. Acad. Sci. USA* 82:488-492; Kunkel *et al.* (1987) *Methods in Enzymol.* 154:367-382; US Patent No. 4,873,192; Walker and Gaastra, eds. (1983) *Techniques in Molecular Biology* (MacMillan Publishing Company, New York) and the references cited therein. Guidance as to appropriate amino acid substitutions that do not affect biological activity of the protein of interest may be found in the model of Dayhoff *et al.* (1978) *Atlas of Protein Sequence and Structure* (Natl. Biomed. Res. Found., Washington, D.C.), herein incorporated by reference. Conservative substitutions, such as exchanging one amino acid with another having similar properties, may be preferred.

Thus, the genes and nucleotide sequences of the invention include both the naturally occurring sequences as well as mutant forms. Likewise, the proteins of the invention encompass both naturally occurring proteins as well as variations and modified forms thereof. Such variants will continue to possess the desired ability to enhance resistance to pathogens when their expression is altered. Obviously, the mutations that will be made in the DNA encoding the variant must not place the sequence out of reading frame and preferably will not create complementary regions that could produce secondary mRNA structure. See, EP Patent Application Publication No. 75,444.

The deletions, insertions, and substitutions of the protein sequences encompassed herein are not expected to produce radical changes in the characteristics of the protein. However, when it is difficult to predict the exact effect of the substitution, deletion, or insertion in advance of doing so, one skilled in the art will appreciate that the effect will be evaluated by routine screening assays. That is, the activity can be evaluated by an enhanced resistance to pathogens when the expression of the protein sequences is altered.

Variant nucleotide sequences and proteins also encompass sequences and proteins derived from a mutagenic and recombinogenic procedure such as DNA shuffling. With such a procedure, one or more different *Mlo* coding sequences can be manipulated to create a new *Mlo* coding sequence possessing the desired properties. In this manner, libraries of recombinant polynucleotides are generated from a population of related sequence polynucleotides comprising

sequence regions that have substantial sequence identity and can be homologously recombined *in vitro* or *in vivo*. For example, using this approach, sequence motifs encoding a domain of interest may be shuffled between the *Mlo* gene of the invention and other known genes involved in pathogen resistance to
5 obtain a new gene coding for a protein with an improved property of interest, such as an increased K_m in the case of an enzyme. Strategies for such DNA shuffling are known in the art. See, for example, Stemmer (1994) *Proc. Natl. Acad. Sci. USA* 91:10747-10751; Stemmer (1994) *Nature* 370:389-391; Cramer *et al.* (1997) *Nature Biotech.* 15:436-438; Moore *et al.* (1997) *J. Mol. Biol.*
10 272:336-347; Zhang *et al.* (1997) *Proc. Natl. Acad. Sci. USA* 94:4504-4509; Cramer *et al.* (1998) *Nature* 391:288-291; and U.S. Patent Nos. 5,605,793 and 5,837,458.

The maize *Mlo* homologues are associated with disease related loci as shown in Table 3. Mapping information of the sequences are given in Table 5.
15 The maize homologue proteins are predicted to be membrane-anchored by at least six, and possibly seven membrane-spanning helices. The maize sequences find use in negative control function of the MLO protein in leaf cell death and in the onset of pathogen defense. Generally, the methods of the invention take advantage of the absence of MLO to prime responsiveness of the plant to
20 disease.

The nucleotide sequences of the invention can be used to isolate corresponding sequences from other organisms, particularly other plants, more particularly other monocots. In this manner, methods such as PCR, hybridization, and the like can be used to identify such sequences based on their
25 sequence homology to the sequences set forth herein. Sequences isolated based on their sequence identity to the entire *Mlo* sequences set forth herein or to fragments thereof are encompassed by the present invention.

In a PCR approach, oligonucleotide primers can be designed for use in PCR reactions to amplify corresponding DNA sequences from cDNA or
30 genomic DNA extracted from any plant of interest. Methods for designing PCR primers and PCR cloning are generally known in the art and are disclosed in Sambrook *et al.* (1989) *Molecular Cloning: A Laboratory Manual* (2d ed., Cold Spring Harbor Laboratory Press, Plainview, New York). See also Innis *et al.*,

eds. (1990) *PCR Protocols: A Guide to Methods and Applications* (Academic Press, New York); Innis and Gelfand, eds. (1995) *PCR Strategies* (Academic Press, New York); and Innis and Gelfand, eds. (1999) *PCR Methods Manual* (Academic Press, New York). Known methods of PCR include, but are not
5 limited to, methods using paired primers, nested primers, single specific primers, degenerate primers, gene-specific primers, vector-specific primers, partially-mismatched primers, and the like.

In hybridization techniques, all or part of a known nucleotide sequence is used as a probe that selectively hybridizes to other corresponding nucleotide
10 sequences present in a population of cloned genomic DNA fragments or cDNA fragments (*i.e.*, genomic or cDNA libraries) from a chosen organism. The hybridization probes may be genomic DNA fragments, cDNA fragments, RNA fragments, or other oligonucleotides, and may be labeled with a detectable group such as ³²P, or any other detectable marker. Thus, for example, probes
15 for hybridization can be made by labeling synthetic oligonucleotides based on the *Mlo* sequences of the invention. Methods for preparation of probes for hybridization and for construction of cDNA and genomic libraries are generally known in the art and are disclosed in Sambrook *et al.* (1989) *Molecular Cloning: A Laboratory Manual* (2d ed., Cold Spring Harbor Laboratory Press,
20 Plainview, New York).

For example, the entire sequence of the *Mlo* nucleotide sequences disclosed herein, or one or more portions thereof, may be used as a probe capable of specifically hybridizing to corresponding *Mlo* sequences and messenger RNAs. To achieve specific hybridization under a variety of
25 conditions, such probes include sequences that are unique among *Mlo* sequences and are preferably at least about 10 nucleotides in length, and most preferably at least about 20 nucleotides in length. Such probes may be used to amplify corresponding *Mlo* sequences from a chosen plant by PCR. This technique may be used to isolate additional coding sequences from a desired
30 plant or as a diagnostic assay to determine the presence of coding sequences in a plant. Hybridization techniques include hybridization screening of plated DNA libraries (either plaques or colonies; see, for example, Sambrook *et al.*

(1989) *Molecular Cloning: A Laboratory Manual* (2d ed., Cold Spring Harbor Laboratory Press, Plainview, New York).

Hybridization of such sequences may be carried out under stringent conditions. By "stringent conditions" or "stringent hybridization conditions" is intended conditions under which a probe will hybridize to its target sequence to a detectably greater degree than to other sequences (e.g., at least 2-fold over background). Stringent conditions are sequence-dependent and will be different in different circumstances. By controlling the stringency of the hybridization and/or washing conditions, target sequences that are 100% complementary to the probe can be identified (homologous probing). Alternatively, stringency conditions can be adjusted to allow some mismatching in sequences so that lower degrees of similarity are detected (heterologous probing). Generally, a probe is less than about 1000 nucleotides in length, preferably less than 500 nucleotides in length.

Typically, stringent conditions will be those in which the salt concentration is less than about 1.5 M Na ion, typically about 0.01 to 1.0 M Na ion concentration (or other salts) at pH 7.0 to 8.3 and the temperature is at least about 30°C for short probes (e.g., 10 to 50 nucleotides) and at least about 60°C for long probes (e.g., greater than 50 nucleotides). Stringent conditions may also be achieved with the addition of destabilizing agents such as formamide. Exemplary low stringency conditions include hybridization with a buffer solution of 30 to 35% formamide, 1 M NaCl, 1% SDS (sodium dodecyl sulphate) at 37°C, and a wash in 1X to 2X SSC (20X SSC = 3.0 M NaCl/0.3 M trisodium citrate) at 50 to 55°C. Exemplary moderate stringency conditions include hybridization in 40 to 45% formamide, 1.0 M NaCl, 1% SDS at 37°C, and a wash in 0.5X to 1X SSC at 55 to 60°C. Exemplary high stringency conditions include hybridization in 50% formamide, 1 M NaCl, 1% SDS at 37°C, and a wash in 0.1X SSC at 60 to 65°C.

Specificity is typically the function of post-hybridization washes, the critical factors being the ionic strength and temperature of the final wash solution. For DNA-DNA hybrids, the T_m can be approximated from the equation of Meinkoth and Wahl (1984) *Anal. Biochem.* 138:267-284: $T_m = 81.5^\circ\text{C} + 16.6 (\log M) + 0.41 (\%GC) - 0.61 (\% \text{ form}) - 500/L$; where M is the

molarity of monovalent cations, %GC is the percentage of guanosine and cytosine nucleotides in the DNA, % form is the percentage of formamide in the hybridization solution, and L is the length of the hybrid in base pairs. The T_m is the temperature (under defined ionic strength and pH) at which 50% of a complementary target sequence hybridizes to a perfectly matched probe. T_m is reduced by about 1°C for each 1% of mismatching; thus, T_m , hybridization, and/or wash conditions can be adjusted to hybridize to sequences of the desired identity. For example, if sequences with $\geq 90\%$ identity are sought, the T_m can be decreased 10°C. Generally, stringent conditions are selected to be about 5°C lower than the thermal melting point (T_m) for the specific sequence and its complement at a defined ionic strength and pH. However, severely stringent conditions can utilize a hybridization and/or wash at 1, 2, 3, or 4°C lower than the thermal melting point (T_m); moderately stringent conditions can utilize a hybridization and/or wash at 6, 7, 8, 9, or 10°C lower than the thermal melting point (T_m); low stringency conditions can utilize a hybridization and/or wash at 11, 12, 13, 14, 15, or 20°C lower than the thermal melting point (T_m). Using the equation, hybridization and wash compositions, and desired T_m , those of ordinary skill will understand that variations in the stringency of hybridization and/or wash solutions are inherently described. If the desired degree of mismatching results in a T_m of less than 45°C (aqueous solution) or 32°C (formamide solution), it is preferred to increase the SSC concentration so that a higher temperature can be used. An extensive guide to the hybridization of nucleic acids is found in Tijssen (1993) *Laboratory Techniques in Biochemistry and Molecular Biology—Hybridization with Nucleic Acid Probes*, Part I, Chapter 2 (Elsevier, New York); and Ausubel *et al.*, eds. (1995) *Current Protocols in Molecular Biology*, Chapter 2 (Greene Publishing and Wiley-Interscience, New York). See Sambrook *et al.* (1989) *Molecular Cloning: A Laboratory Manual* (2d ed., Cold Spring Harbor Laboratory Press, Plainview, New York).

In general, sequences that encode for a Mlo protein and hybridize to the Mlo sequences disclosed herein will be at least 40% to 50% homologous, about 60% to 70% homologous, and even about 80%, 85%, 90%, 95% to 98% homologous or more with the disclosed sequences. That is, the sequence

similarity of sequences may range, sharing at least about 40% to 50%, about 60% to 70%, and even about 80%, 85%, 90%, 95% to 98% sequence similarity.

The following terms are used to describe the sequence relationships between two or more nucleic acids or polynucleotides: (a) "reference sequence",
5 (b) "comparison window", (c) "sequence identity", (d) "percentage of sequence identity", and (e) "substantial identity".

(a) As used herein, "reference sequence" is a defined sequence used as a basis for sequence comparison. A reference sequence may be a subset or the entirety of a specified sequence; for example, as a segment of a full-length
10 cDNA or gene sequence, or the complete cDNA or gene sequence.

(b) As used herein, "comparison window" makes reference to a contiguous and specified segment of a polynucleotide sequence, wherein the polynucleotide sequence in the comparison window may comprise additions or deletions (i.e., gaps) compared to the reference sequence (which does not
15 comprise additions or deletions) for optimal alignment of the two sequences. Generally, the comparison window is at least 20 contiguous nucleotides in length, and optionally can be 30, 40, 50, 100, or longer. Those of skill in the art understand that to avoid a high similarity to a reference sequence due to inclusion of gaps in the polynucleotide sequence a gap penalty is typically
20 introduced and is subtracted from the number of matches.

Methods of alignment of sequences for comparison are well known in the art. Optimal alignment of sequences for comparison may be conducted by the local homology algorithm of Smith *et al.* (1981) *Adv. Appl. Math.* 2:482; by the homology alignment algorithm of Needleman *et al.* (1970) *J. Mol. Biol.*
25 48:443; by the search for similarity method of Pearson *et al.* (1988) *Proc. Natl. Acad. Sci.* 85:2444; by computerized implementations of these algorithms, including, but not limited to: CLUSTAL in the PC/Gene program by Intelligenetics, Mountain View, California; GAP, BESTFIT, BLAST, FASTA, and TFASTA in the Wisconsin Genetics Software Package, Genetics Computer
30 Group (GCG), 575 Science Drive, Madison, Wisconsin, USA; the CLUSTAL program is well described by Higgins *et al.* (1988) *Gene* 73:237-244 (1988); Higgins *et al.* (1989) *CABIOS* 5:151-153; Corpet *et al.* (1988) *Nucleic Acids Res.* 16:10881-90; Huang *et al.* (1992) *Computer Applications in the*

Biosciences 8:155-65, and Person *et al.* (1994) *Meth. Mol. Biol.* 24:307-331; preferred computer alignment methods also include the BLASTP, BLASTN, and BLASTX algorithms (see Altschul *et al.* (1990) *J. Mol. Biol.* 215:403-410). Alignment is also often performed by inspection and manual alignment.

5 (c) As used herein, "sequence identity" or "identity" in the context of two nucleic acid or polypeptide sequences makes reference to the residues in the two sequences that are the same when aligned for maximum correspondence over a specified comparison window. When percentage of sequence identity is used in reference to proteins it is recognized that residue positions which are not
10 identical often differ by conservative amino acid substitutions, where amino acid residues are substituted for other amino acid residues with similar chemical properties (e.g., charge or hydrophobicity) and therefore do not change the functional properties of the molecule. When sequences differ in conservative substitutions, the percent sequence identity may be adjusted upwards to correct
15 for the conservative nature of the substitution. Sequences that differ by such conservative substitutions are said to have "sequence similarity" or "similarity". Means for making this adjustment are well known to those of skill in the art. Typically this involves scoring a conservative substitution as a partial rather than a full mismatch, thereby increasing the percentage sequence identity.
20 Thus, for example, where an identical amino acid is given a score of 1 and a non-conservative substitution is given a score of zero, a conservative substitution is given a score between zero and 1. The scoring of conservative substitutions is calculated, e.g., as implemented in the program PC/GENE (Intelligenetics, Mountain View, California).

25 (d) As used herein, "percentage of sequence identity" means the value determined by comparing two optimally aligned sequences over a comparison window, wherein the portion of the polynucleotide sequence in the comparison window may comprise additions or deletions (i.e., gaps) as compared to the reference sequence (which does not comprise additions or
30 deletions) for optimal alignment of the two sequences. The percentage is calculated by determining the number of positions at which the identical nucleic acid base or amino acid residue occurs in both sequences to yield the number of matched positions, dividing the number of matched positions by the total

number of positions in the window of comparison, and multiplying the result by 100 to yield the percentage of sequence identity.

(e)(i) The term "substantial identity" of polynucleotide sequences means that a polynucleotide comprises a sequence that has at least 70%
5 sequence identity, preferably at least 80%, more preferably at least 90%, and most preferably at least 95%, compared to a reference sequence using one of the alignment programs described using standard parameters. One of skill in the art will recognize that these values can be appropriately adjusted to determine
10 corresponding identity of proteins encoded by two nucleotide sequences by taking into account codon degeneracy, amino acid similarity, reading frame positioning, and the like. Substantial identity of amino acid sequences for these purposes normally means sequence identity of at least 60%, more preferably at least 70%, 80%, 90%, and most preferably at least 95%.

Another indication that nucleotide sequences are substantially identical
15 is if two molecules hybridize to each other under stringent conditions. Generally, stringent conditions are selected to be about 5°C lower than the thermal melting point (T_m) for the specific sequence at a defined ionic strength and pH. However, stringent conditions encompass temperatures in the range of about 1°C to about 20°C, depending upon the desired degree of stringency as
20 otherwise qualified herein. Nucleic acids that do not hybridize to each other under stringent conditions are still substantially identical if the polypeptides they encode are substantially identical. This may occur, e.g., when a copy of a nucleic acid is created using the maximum codon degeneracy permitted by the genetic code. One indication that two nucleic acid sequences are substantially
25 identical is when the polypeptide encoded by the first nucleic acid is immunologically cross reactive with the polypeptide encoded by the second nucleic acid.

(e)(ii) The term "substantial identity" in the context of a peptide indicates that a peptide comprises a sequence with at least 70% sequence
30 identity to a reference sequence, preferably 80%, more preferably 85%, most preferably at least 90% or 95% sequence identity to the reference sequence over a specified comparison window. Preferably, optimal alignment is conducted using the homology alignment algorithm of Needleman *et al.* (1970) *J. Mol.*

Biol. 48:443. An indication that two peptide sequences are substantially identical is that one peptide is immunologically reactive with antibodies raised against the second peptide. Thus, a peptide is substantially identical to a second peptide, for example, where the two peptides differ only by a conservative substitution. Peptides that are "substantially similar" share sequences as noted above except that residue positions that are not identical may differ by conservative amino acid changes.

The invention is drawn to methods for creating or enhancing resistance in a plant to plant pests by modulating the activity of *Mlo* genes in the plant. While the invention is not bound by any particular mechanism of action, it is believed that the methods of the invention will result in broad-based resistance in the modified plant. Accordingly, the methods are also useful in protecting plants against fungal pathogens, viruses, nematodes, insects and the like.

By "modulating activity" is intended that the expression of the *Mlo* gene is altered in some manner. Such modulation (increase or decrease) of expression results in enhanced resistance to pathogens. Generally, the methods of the invention will result in a decrease in the native protein or in protein activity. Thus, plants and plant cells are obtained having altered levels of MLO protein, preferably a decrease in protein levels. Such plants, plant cells and plant tissues are "modified" in that MLO protein levels are altered. As noted below, various methods are available for creating modified plants, plant cells and plant tissues including transformation and transfection leading to altered *Mlo* expression in the modified plant, plant cell or tissue.

The invention is drawn to compositions and methods for inducing resistance in a plant to plant pests. Accordingly, the compositions and methods are also useful in protecting plants against fungal pathogens, viruses, nematodes, insects and the like.

By "disease resistance" is intended that the plants avoid the disease symptoms that are the outcome of plant-pathogen interactions. That is, pathogens are prevented from causing plant diseases and the associated disease symptoms, or alternatively, the disease symptoms caused by the pathogen is minimized or lessened. The methods of the invention can be utilized to protect

plants from disease, particularly those diseases that are caused by plant pathogens.

Pathogens of the invention include, but are not limited to, viruses or viroids, bacteria, insects, nematodes, fungi, and the like. Viruses include any plant virus, for example, tobacco or cucumber mosaic virus, ringspot virus, necrosis virus, maize dwarf mosaic virus, etc. Specific fungal and viral pathogens for the major crops include: Soybeans: *Phytophthora megasperma* fsp. *glycinea*, *Macrophomina phaseolina*, *Rhizoctonia solani*, *Sclerotinia sclerotiorum*, *Fusarium oxysporum*, *Diaporthe phaseolorum* var. *sojae* (10) (*Phomopsis sojae*), *Diaporthe phaseolorum* var. *caulivora*, *Sclerotium rolfsii*, *Cercospora kikuchii*, *Cercospora sojina*, *Peronospora manshurica*, *Colletotrichum dematium* (*Colletotrichum truncatum*), *Corynespora cassiicola*, *Septoria glycines*, *Phyllosticta sojicola*, *Alternaria alternata*, *Pseudomonas syringae* p.v. *glycinea*, *Xanthomonas campestris* p.v. *phaseoli*, *Microsphaera* (15) *diffusa*, *Fusarium semitectum*, *Phialophora gregata*, Soybean mosaic virus, *Glomerella glycines*, Tobacco Ring spot virus, Tobacco Streak virus, *Phakopsora pachyrhizi*, *Pythium aphanidermatum*, *Pythium ultimum*, *Pythium debaryanum*, Tomato spotted wilt virus, *Heterodera glycines* *Fusarium solani*; Canola: *Albugo candida*, *Alternaria brassicae*, *Leptosphaeria maculans*, (20) *Rhizoctonia solani*, *Sclerotinia sclerotiorum*, *Mycosphaerella brassicicola*, *Pythium ultimum*, *Peronospora parasitica*, *Fusarium roseum*, *Alternaria alternata*; Alfalfa: *Clavibacter michiganese* subsp. *insidiosum*, *Pythium ultimum*, *Pythium irregulare*, *Pythium splendens*, *Pythium debaryanum*, *Pythium aphanidermatum*, *Phytophthora megasperma*, *Peronospora* (25) *trifoliorum*, *Phoma medicaginis* var. *medicaginis*, *Cercospora medicaginis*, *Pseudopeziza medicaginis*, *Leptotrochila medicaginis*, *Fusarium*, *Xanthomonas campestris* p.v. *alfalfae*, *Aphanomyces euteiches*, *Stemphylium herbarum*, *Stemphylium alfalfae*; Wheat: *Pseudomonas syringae* p.v. *atrofaciens*, *Urocystis agropyri*, *Xanthomonas campestris* p.v. *translucens*, *Pseudomonas* (30) *syringae* p.v. *syringae*, *Alternaria alternata*, *Cladosporium herbarum*, *Fusarium graminearum*, *Fusarium avenaceum*, *Fusarium culmorum*, *Ustilago tritici*, *Ascochyta tritici*, *Cephalosporium gramineum*, *Colletotrichum graminicola*, *Erysiphe graminis* f.sp. *tritici*, *Puccinia graminis* f.sp. *tritici*,

- Nematodes include parasitic nematodes such as root-knot, cyst, lesion,
 20 and reniform nematodes, etc.

- Insect pests include insects selected from the orders Coleoptera, Diptera,
 Hymenoptera, Lepidoptera, Mallophaga, Homoptera, Hemiptera, Orthoptera,
 Thysanoptera, Dermaptera, Isoptera, Anoplura, Siphonaptera, Trichoptera, etc.,
 particularly Coleoptera and Lepidoptera. Insect pests of the invention for the
 25 major crops include: Maize: *Ostrinia nubilalis*, European corn borer; *Agrotis*
ipsilon, black cutworm; *Helicoverpa zea*, corn earworm; *Spodoptera*
frugiperda, fall armyworm; *Diatraea grandiosella*, southwestern corn borer;
Elasmopalpus lignosellus, lesser cornstalk borer; *Diatraea saccharalis*,
 sugarcane borer; *Diabrotica virgifera*, western corn rootworm; *Diabrotica*
 30 *longicornis barberi*, northern corn rootworm; *Diabrotica undecimpunctata*
howardi, southern corn rootworm; *Melanotus* spp., wireworms; *Cyclocephala*
borealis, northern masked chafer (white grub); *Cyclocephala immaculata*,
 southern masked chafer (white grub); *Popillia japonica*, Japanese beetle;

- Chaetocnema pulicaria*, corn flea beetle; *Sphenophorus maidis*, maize billbug; *Rhopalosiphum maidis*, corn leaf aphid; *Anuraphis maidiradicis*, corn root aphid; *Blissus leucopterus leucopterus*, chinch bug; *Melanoplus femurrubrum*, redlegged grasshopper; *Melanoplus sanguinipes*, migratory grasshopper;
- 5 *Hylemya platura*, seedcorn maggot; *Agromyza parvicornis*, corn blot leafminer; *Anaphothrips obscurus*, grass thrips; *Solenopsis milesta*, thief ant; *Tetranychus urticae*, twospotted spider mite; Sorghum: *Chilo partellus*, sorghum borer; *Spodoptera frugiperda*, fall armyworm; *Helicoverpa zea*, corn earworm; *Elasmopalpus lignosellus*, lesser cornstalk borer; *Feltia subterranea*, granulate
- 10 cutworm; *Phyllophaga crinita*, white grub; *Eleodes*, *Conoderus*, and *Aeolus* spp., wireworms; *Oulema melanopus*, cereal leaf beetle; *Chaetocnema pulicaria*, corn flea beetle; *Sphenophorus maidis*, maize billbug; *Rhopalosiphum maidis*, corn leaf aphid; *Sipha flava*, yellow sugarcane aphid; *Blissus leucopterus leucopterus*, chinch bug; *Contarinia sorghicola*, sorghum
- 15 midge; *Tetranychus cinnabarinus*, carmine spider mite; *Tetranychus urticae*, twospotted spider mite; Wheat: *Pseudaletia unipunctata*, army worm; *Spodoptera frugiperda*, fall armyworm; *Elasmopalpus lignosellus*, lesser cornstalk borer; *Agrotis orthogonia*, western cutworm; *Elasmopalpus lignosellus*, lesser cornstalk borer; *Oulema melanopus*, cereal leaf beetle;
- 20 *Hypera punctata*, clover leaf weevil; *Diabrotica undecimpunctata howardi*, southern corn rootworm; Russian wheat aphid; *Schizaphis graminum*, greenbug; *Macrosiphum avenae*, English grain aphid; *Melanoplus femurrubrum*, redlegged grasshopper; *Melanoplus differentialis*, differential grasshopper; *Melanoplus sanguinipes*, migratory grasshopper; *Mayetiola destructor*, Hessian
- 25 fly; *Sitodiplosis mosellana*, wheat midge; *Meromyza americana*, wheat stem maggot; *Hylemya coarctata*, wheat bulb fly; *Frankliniella fusca*, tobacco thrips; *Cephus cinctus*, wheat stem sawfly; *Aceria tulipae*, wheat curl mite; Sunflower: *Suleima helianthana*, sunflower bud moth; *Homoeosoma electellum*, sunflower
- 30 beetle; *zygogramma exclamationis*, sunflower beetle; *Bothyrus gibbosus*, carrot beetle; *Neolasioptera murtfeldtiana*, sunflower seed midge; Cotton: *Heliothis virescens*, cotton budworm; *Helicoverpa zea*, cotton bollworm; *Spodoptera exigua*, beet armyworm; *Pectinophora gossypiella*, pink bollworm; *Anthonomus grandis grandis*, boll weevil; *Aphis gossypii*, cotton aphid; *Pseudatomoscelis*

seriatus, cotton fleahopper; *Trialeurodes abutilonea*, bandedwinged whitefly;
Lygus lineolaris, tarnished plant bug; *Melanoplus femurrubrum*, redlegged
 grasshopper; *Melanoplus differentialis*, differential grasshopper; *Thrips tabaci*,
 onion thrips; *Frankliniella fusca*, tobacco thrips; *Tetranychus cinnabarinus*,
 5 carmine spider mite; *Tetranychus urticae*, twospotted spider mite; Rice:
Diatraea saccharalis, sugarcane borer; *Spodoptera frugiperda*, fall armyworm;
Helicoverpa zea, corn earworm; *Colaspis brunnea*, grape colaspis;
Lissorhoptrus oryzophilus, rice water weevil; *Sitophilus oryzae*, rice weevil;
Nephotettix nigropictus, rice leafhopper; *Blissus leucopterus leucopterus*,
 10 chinch bug; *Acrosternum hilare*, green stink bug; Soybean: *Pseudoplusia*
includens, soybean looper; *Anticarsia gemmatilis*, velvetbean caterpillar;
Plathypena scabra, green cloverworm; *Ostrinia nubilalis*, European corn borer;
Agrotis ipsilon, black cutworm; *Spodoptera exigua*, beet armyworm; *Heliothis*
virescens, cotton budworm; *Helicoverpa zea*, cotton bollworm; *Epilachna*
 15 *varivestis*, Mexican bean beetle; *Myzus persicae*, green peach aphid; *Empoasca*
fabae, potato leafhopper; *Acrosternum hilare*, green stink bug; *Melanoplus*
femurrubrum, redlegged grasshopper; *Melanoplus differentialis*, differential
 grasshopper; *Hylemya platura*, seedcorn maggot; *Sericothrips variabilis*,
 soybean thrips; *Thrips tabaci*, onion thrips; *Tetranychus turkestani*, strawberry
 20 spider mite; *Tetranychus urticae*, twospotted spider mite; Barley: *Ostrinia*
nubilalis, European corn borer; *Agrotis ipsilon*, black cutworm; *Schizaphis*
graminum, greenbug; *Blissus leucopterus leucopterus*, chinch bug; *Acrosternum*
hilare, green stink bug; *Euschistus servus*, brown stink bug; *Delia platura*,
 seedcorn maggot; *Mayetiola destructor*, Hessian fly; *Petrobia latens*, brown
 25 wheat mite; Oil Seed Rape: *Brevicoryne brassicae*, cabbage aphid; *Phyllotreta*
cruciferae, Flea beetle; *Mamestra configurata*, Bertha armyworm; *Plutella*
xylostella, Diamond-back moth; *Delia* ssp., Root maggots.

The present invention exploits the use of *Mlo* genes. The *Mlo* sequences
 provided herein can be utilized to alter the expression of native *Mlo* genes in
 30 plants. The *mlo* mutation confers recessive resistance to pathogens. Broad
 spectrum resistance in plants can be enhanced by defective *Mlo* genes.

While the invention is not bound by any model, *Mlo* could have a
 negative control function in leaf cell death. In this model, *Mlo* would suppress a

default cell suicide program in foliar tissue. Also, the MLO protein could have a specific negative regulatory function which works by down-regulating multiple disease-related functions. In this instance, spontaneous cell death in *mlo* mutant genotypes merely represents cell death because of accumulating
5 activation of defense responses.

Several methods are available in the art for modulating the activity of *Mlo* genes. *Mlo* antisense sequences can be expressed in the plant cell. Such sequences will function to decrease expression of the maize *Mlo* genes as well as *Mlo* genes in other plants where the *Mlo* sequences share sequence identity.

10 It is recognized that with these nucleotide sequences, antisense constructions, complementary to at least a portion of the messenger RNA (mRNA) for the *Mlo* sequences can be constructed. Antisense nucleotides are constructed to hybridize with the corresponding mRNA. Modifications of the antisense sequences may be made as long as the sequences hybridize to and
15 interfere with expression of the corresponding mRNA. In this manner, antisense constructions having 70%, preferably 80%, more preferably 85% sequence similarity to the corresponding antisensed sequences may be used. Furthermore, portions of the antisense nucleotides may be used to disrupt the expression of the target gene. Generally, sequences of at least 50 nucleotides,
20 100 nucleotides, 200 nucleotides, or greater may be used.

The antisense construct may be proximal to the 5'-terminus or capping site, downstream from the capping site, between the capping site and the initiation codon and may cover all or a portion of the non-coding region. Additionally, the sequence may bridge the non-coding and coding region, be
25 complementary to all or part of the coding region, to the 3'-terminus of the coding region, or complementary to the 3'-untranslated region of the mRNA.

It is recognized that the particular site to which the antisense sequence binds and the length of the antisense sequence will vary depending upon the degree of inhibition desired, the uniqueness of the sequence, the stability of the
30 antisense sequence, and the like. See, for example, U.S. Patent Nos. 5,453,566; 5,530,192; and 5,728,926; all of which are herein incorporated by reference.

The nucleotide sequences of the present invention may also be used in the sense orientation to suppress the expression of endogenous genes in plants.

Methods for suppressing gene expression in plants using nucleotide sequences in the sense orientation are known in the art. The methods generally involve transforming plants with a DNA construct comprising a promoter that drives expression in a plant operably linked to at least a portion of a nucleotide
5 sequence that corresponds to the transcript of the endogenous gene. Typically, such a nucleotide sequence has substantial sequence identity to the sequence of the transcript of the endogenous gene, preferably greater than about 65% sequence identity, more preferably greater than about 85% sequence identity, most preferably greater than about 95% sequence identity. See, U.S. Patent
10 Nos. 5,283,184 and 5,034,323; herein incorporated by reference.

Individual *Mlo* genes or sets of *Mlo* genes can be rendered nonfunctional by mutagenesis. Such mutagenesis techniques include transposon disruption and recovery of such disruptions by reverse genetics approaches. Likewise, transformation-mediated mutagenesis may be utilized.

15 Disruption may be accomplished by transformation with gene replacement or gene truncation-disruption. See, for example, Bowen *et al.* (1995) *Mol. Gen. Gent.* 246:196-205; Walz *et al.* (1993) *Curr. Gent.* 25:421-427; Sweigard *et al.* (1992) *Mol. Gen. Gent.* 232:183-190; Hohn and Desjardins (1992) *Mol. Plant Microbe Interact* 5:249-256; Weber and Laitner (1994) *Curr.*
20 *Gent.* 26:461-467; Templeton *et al.* (1994) *Gene* 142:141-146; Grolach *et al.* (1998) *Appl. Environ. Microbiol.* 64:385-391; Schaeffer *et al.* (1994) *Appl. Environ. Microbiol.* 60:594-598; and the like, herein incorporated by reference. See also, Kempin *et al.* (1997) *Nature* 389:802-803 and Koncz *et al.* (1992) *Plant Mol. Biol.* 20:963-976.

25 Alternatively, the naturally occurring *Mlo* sequence or sequences may be modified by site-directed mutagenesis. Such methods may be utilized to induce specific alterations in targeted genes. One means for site-directed mutagenesis includes targeting modification or mutation of the *Mlo* sequences by homologous recombination. The method involves the use of RNA-DNA
30 hybrid oligonucleotides. Such nucleotides exploit the natural recombinogenicity of RNA-DNA hybrids. The oligonucleotides are duplex oligonucleotides that share homology with at least one *Mlo* sequence. While any region of the *Mlo* sequence can be targeted, it may be preferable to target

the 5' region of the *Mlo* sequence. See, for example, U.S. Patent No. 5,565,350 that describes chimeric oligonucleotides useful for targeted gene correction for use in cultured mammalian cells; as well as U.S. provisional application Serial No. 06/065,628 drawn to gene manipulation in plant cells, herein incorporated
5 by reference. Such methods can be used to alter or disrupt the ATG start codon for the gene.

Alternatively, protein coding regions of *Mlo* genes can be altered in such a manner that the gene products or proteins perform their function in a dominant negative manner resulting in a resistant phenotype. See, for example Krylov *et al.* (1997) *Proc. Natl. Acad. Sci. USA* 94:12274-12279.
10

Where the method of the invention relies upon the expression of an altered *Mlo* sequence or an *Mlo* antisense sequence in a plant, a number of promoters can be used. The promoters can be selected from constitutive and/or inducible promoters. Such promoters include those from pathogenesis-related
15 proteins (PR proteins), which are induced following infection by a pathogen; e.g., PR proteins, SAR proteins, beta-1,3-glucanase, chitinase, etc. See, for example, Redolfi *et al.* (1983) *Neth. J. Plant Pathol.* 89:245-254; Uknes *et al.* (1992) *The Plant Cell* 4:645-656; and Van Loon (1985) *Plant Mol. Virol.* 4:111-116. See, also copending application entitled "Inducible Maize promoters",
20 filed and herein incorporated by reference.

Of interest are promoters that are expressed locally at or near the site of pathogen infection. See, for example, Marineau *et al.* (1987) *Plant Mol. Biol.* 9:335-342; Matton *et al.* (1989) *Molecular Plant-Microbe Interactions* 2:325-331; Somsisch *et al.* (1986) *Proc. Natl. Acad. Sci. USA* 83:2427-2430;
25 Somsisch *et al.* (1988) *Molecular and General Genetics* 2:93-98; and Yang, Y (1996) *Proc. Natl. Acad. Sci. USA* 93:14972-14977. See also, Chen *et al.* (1996) *Plant J.* 10:955-966; Zhang and Sing (1994) *Proc. Natl. Acad. Sci. USA* 91:2507-2511; Warner *et al.* (1993) *Plant J.* 3:191-201; Siebertz *et al.* (1989) *Plant Cell* 1:961-968; and the references cited therein. Of particular interest is
30 the inducible promoter for the maize PRms gene, whose expression is induced by the pathogen *Fusarium moniliforme* (see, for example, Cordero *et al.* (1992) *Physiological and Molecular Plant Pathology* 41:189-200).

Constitutive promoters include, for example, the core promoter of the Rsyn7 (copending application serial number 08/661,601), the 35S promoter, the core 35S promoter, and the like. Other constitutive promoters include, for example, U.S. Patent Nos. 5,608,149; 5,608,144; 5,604,121; 5,569,597; 5,466,785; 5,399,680; 5,268,463; 5,608,142. See also, copending application
5 entitled "Constitutive Maize Promoters" Provisional Application Serial No. 60/076,075 filed February 26, 1998, and herein incorporated by reference.

Tissue specific promoters include Yamamoto *et al.* (1997) *Plant J.* 12(2):255-265; Kawamata *et al.* (1997) *Plant Cell Physiol.* 38(7):792-803;
10 Hansen *et al.* (1997) *Mol. Gen Genet.* 254(3):337-343; Russell *et al.* (1997) *Transgenic Res.* 6(2):157-168; Rinehart *et al.* (1996) *Plant Physiol.* 112(3):1331-1341; Van Camp *et al.* (1996) *Plant Physiol.* 112(2):525-535; Canevascini *et al.* (1996) *Plant Physiol.* 112(2):513-524; Yamamoto *et al.* (1994) *Plant Cell Physiol.* 35(5):773-778; Lam (1994) *Results Probl. Cell.*
15 *Differ.* 20:181-196; Orozco *et al.* (1993) *Plant Mol. Biol.* 23(6):1129-1138; Matsuoka *et al.* (1993) *Proc. Natl. Acad. Sci. U.S.A.* 90(20):9586-9590; and Guevara-Garcia *et al.* (1993) *Plant J.* 4(3):495-505.

The methods of the invention can be used with other methods for increasing pathogen resistance in plants. See, for example, Cai *et al.* (1997)
20 *Science* 275:832-834; Roberts and Galloway (1984) *J. Heredity* 75:147-148; Ryerson and Heath (1996) *Plant Cell* 8:393-402 and Dangl *et al.* (1996) *Plant Cell* 8:1793-1807.

Altered *Mlo* sequences or antisense *Mlo* sequences of the invention can be introduced into any plant. The sequences to be introduced may be used in
25 expression cassettes for expression in any plant of interest where expression in the plant cell is necessary. In other instances, such as for recombination, oligonucleotides are synthesized, purified and introduced into the plant cell.

Where expression cassettes are needed, such expression cassettes will comprise a transcriptional initiation region linked to the coding sequence or
30 antisense sequence of the nucleotide of interest. Such an expression cassette is provided with a plurality of restriction sites for insertion of the sequence to be under the transcriptional regulation of the regulatory regions. The expression cassette may additionally contain selectable marker genes.

The transcriptional initiation region, the promoter, may be native or analogous or foreign or heterologous to the plant host. Additionally, the promoter may be the natural sequence or alternatively a synthetic sequence. By foreign is intended that the transcriptional initiation region is not found in the native plant into which the transcriptional initiation region is introduced. As used herein a chimeric gene comprises a coding sequence operably linked to a transcription initiation region that is heterologous to the coding sequence.

While it may be preferable to express the sequences using heterologous promoters, the native promoter sequences may be used. Such constructs would change expression levels of a MLO protein in the plant or plant cell. Thus, the phenotype of the plant or plant cell is altered.

The transcriptional cassette will include in the 5'-3' direction of transcription, a transcriptional and translational initiation region, a DNA sequence of interest, and a transcriptional and translational termination region functional in plants. The termination region may be native with the transcriptional initiation region, may be native with the DNA sequence of interest, or may be derived from another source. Convenient termination regions are available from the Ti-plasmid of *A. tumefaciens*, such as the octopine synthase and nopaline synthase termination regions. See also, Guerineau *et al.* (1991) *Mol. Gen. Genet.* 262:141-144; Proudfoot (1991) *Cell* 64:671-674; Sanfacon *et al.* (1991) *Genes Dev.* 5:141-149; Mogen *et al.* (1990) *Plant Cell.* 2:1261-1272; Munroe *et al.* (1990) *Gene* 91:151-158; Ballas *et al.* (1989) *Nucleic Acids Res.* 17:7891-7903; Joshi *et al.* (1987) *Nucleic Acid Res.* 15:9627-9639.

Nucleotide sequences of the invention are provided in expression cassettes for expression in the plant of interest. The cassette will include 5' and 3' regulatory sequences operably linked to the sequence of interest. The cassette may additionally contain at least one additional sequence to be cotransformed into the organism. Alternatively, the additional sequence(s) can be provided on another expression cassette.

Where appropriate, the gene(s) may be optimized for increased expression in the transformed plant. That is, the genes can be synthesized using plant-preferred codons for improved expression. See, for example, Campbell

and Gowri (1990) *Plant Physiol.* 92:1-11 for a discussion of host-preferred codon usage. Methods are available in the art for synthesizing plant-preferred genes. See, for example, U.S. Patent Nos. 5,380,831, 5,436,391, and Murray *et al.* (1989) *Nucleic Acids Res.* 17:477-498, herein incorporated by reference.

5 Additional sequence modifications are known to enhance gene expression in a cellular host. These include elimination of sequences encoding spurious polyadenylation signals, exon-intron splice site signals, transposon-like repeats, and other such well-characterized sequences that may be deleterious to gene expression. The G-C content of the sequence may be adjusted to levels
10 average for a given cellular host, as calculated by reference to known genes expressed in the host cell. When possible, the sequence is modified to avoid predicted hairpin secondary mRNA structures.

The expression cassettes may additionally contain 5' leader sequences in the expression cassette construct. Such leader sequences can act to enhance
15 translation. Translation leaders are known in the art and include: picornavirus leaders, for example, EMCV leader (Encephalomyocarditis 5' noncoding region) (Elroy-Stein *et al.* (1989) *PNAS USA* 86:6126-6130); potyvirus leaders, for example, TEV leader (Tobacco Etch Virus) (Allison *et al.* (1986); MDMV leader (Maize Dwarf Mosaic Virus); *Virology* 154:9-20), and human
20 immunoglobulin heavy-chain binding protein (BiP), (Macejak *et al.* (1991) *Nature* 353:90-94); untranslated leader from the coat protein mRNA of alfalfa mosaic virus (AMV RNA 4) (Jobling *et al.* (1987) *Nature* 325:622-625); tobacco mosaic virus leader (TMV) (Gallie *et al.* (1989) in *Molecular Biology of RNA*, ed. Cech (Liss, New York), pp. 237-256); and maize chlorotic mottle
25 virus leader (MCMV) (Lommel *et al.* (1991) *Virology* 81:382-385). See also, Della-Cioppa *et al.* (1987) *Plant Physiol.* 84:965-968. Other methods known to enhance translation can also be utilized, for example, introns, and the like.

In preparing the expression cassette, the various DNA fragments may be manipulated, so as to provide for the DNA sequences in the proper orientation
30 and, as appropriate, in the proper reading frame. Towards this end, adapters or linkers may be employed to join the DNA fragments or other manipulations may be involved to provide for convenient restriction sites, removal of superfluous DNA, removal of restriction sites, or the like. For this purpose, *in*

vitro mutagenesis, primer repair, restriction, annealing, resubstitutions, e.g. transitions and transversions, may be involved.

The sequences of the present invention can be used to transform or transfect any plant. In this manner, genetically modified plants, plant cells, plant tissue, seed, and the like can be obtained. Transformation protocols as well as protocols for introducing nucleotide sequences into plants may vary depending on the type of plant or plant cell, i.e., monocot or dicot, targeted for transformation. Suitable methods of introducing nucleotide sequences into plant cells and subsequent insertion into the plant genome include microinjection (Crossway *et al.* (1986) *Biotechniques* 4:320-334), electroporation (Riggs *et al.* (1986) *Proc. Natl. Acad. Sci. USA* 83:5602-5606, *Agrobacterium*-mediated transformation (Townsend *et al.*, U.S. Pat No. 5,563,055), direct gene transfer (Paszkowski *et al.* (1984) *EMBO J.* 3:2717-2722), and ballistic particle acceleration (see, for example, Sanford *et al.*, U.S. Patent No. 4,945,050; Tomes *et al.* (1995) "Direct DNA Transfer into Intact Plant Cells via Microprojectile Bombardment," in *Plant Cell, Tissue, and Organ Culture: Fundamental Methods*, ed. Gamborg and Phillips (Springer-Verlag, Berlin); and McCabe *et al.* (1988) *Biotechnology* 6:923-926). Also see Weissinger *et al.* (1988) *Ann. Rev. Genet.* 22:421-477; Sanford *et al.* (1987) *Particulate Science and Technology* 5:27-37 (onion); Christou *et al.* (1988) *Plant Physiol.* 87:671-674 (soybean); McCabe *et al.* (1988) *Bio/Technology* 6:923-926 (soybean); Finer and McMullen (1991) *In Vitro Cell Dev. Chapman *et al.* (Longman, New York), pp. 197-209 (pollen); Kaeppler *et al.* (1990) *Plant Cell Reports* 9:415-418 and Kaeppler *et al.* (1992) *Theor. Appl. Genet.* 84:560-566 (whisker-mediated transformation); D'Halluin *et al.* (1992) *Plant Cell* 4:1495-1505 (electroporation); Li *et al.* (1993) *Plant Cell Reports* 12:250-255 and Christou and Ford (1995) *Annals of Botany* 75:407-413 (rice); Osjoda *et al.* (1996) *Nature Biotechnology* 14:745-750 (maize via *Agrobacterium tumefaciens*); all of which are herein incorporated by reference.

10 The modified plant may be grown into plants in accordance with conventional ways. See, for example, McCormick *et al.* (1986) *Plant Cell Reports*, 5:81-84. These plants may then be grown, and either pollinated with the same transformed strain or different strains, and the resulting hybrid having the desired phenotypic characteristic identified. Two or more generations may
15 be grown to ensure that the subject phenotypic characteristic is stably maintained and inherited and then seeds harvested to ensure the desired phenotype or other property has been achieved.

 The *Mlo* sequences of the invention are also useful as molecular markers. Such markers are useful in breeding programs, particularly those
20 aimed at improving disease resistance. The maize *Mlo* sequences have been mapped to chromosome locations and these positions related to known disease resistance loci.

 The present invention provides a method of genotyping a plant comprising a polynucleotide of the present invention. Preferably, the plant is a
25 monocot, such as maize or sorghum. Genotyping provides a means of distinguishing homologs of a chromosome pair and can be used to differentiate segregants in a plant population. Molecular marker methods can be used for phylogenetic studies, characterizing genetic relationships among crop varieties, identifying crosses or somatic hybrids, localizing chromosomal segments
30 affecting monogenic traits, map based cloning, and the study of quantitative inheritance. See, e.g., *Plant Molecular Biology: A Laboratory Manual*, Chapter 7, Clark, Ed., Springer-Verlag, Berlin (1997). For molecular marker methods, see generally, *The DNA Revolution* by Andrew H. Paterson (1996)

(Chapter 2) in: Genome Mapping in Plants (ed. Andrew H. Paterson) by Academic Press/R. G. Landis Company, Austin, Texas, pp. 7-21.

The particular method of genotyping in the present invention may employ any number of molecular marker analytic techniques such as, but not
5 limited to, restriction fragment length polymorphisms (RFLPs). RFLPs are the product of allelic differences between DNA restriction fragments caused by nucleotide sequence variability. As is well known to those of skill in the art, RFLPs are typically detected by extraction of genomic DNA and digestion with a restriction enzyme. Generally, the resulting fragments are separated according
10 to size and hybridized with a probe; single copy probes are preferred. Restriction fragments from homologous chromosomes are revealed. Differences in fragment size among alleles represent an RFLP. Thus, the present invention further provides a means to follow segregation of a gene or nucleic acid of the present invention as well as chromosomal sequences
15 genetically linked to these genes or nucleic acids using such techniques as RFLP analysis. Linked chromosomal sequences are within 50 centiMorgans (Cm), often within 40 or 30 Cm, preferably within 20 or 10 Cm, more preferably within 5, 3, 2, or 1 Cm of a gene.

In the present invention, the nucleic acid probes employed for molecular
20 marker mapping of plant nuclear genomes selectively hybridize, under selective hybridization conditions, to a gene encoding a polynucleotide of the present invention. In preferred embodiments, the probes are selected from polynucleotides of the present invention. Typically, these probes are cDNA probes or *PstI* genomic clones. The length of the probes is discussed in greater
25 detail, *supra*, but are typically at least 15 bases in length, more preferably at least 20, 25, 30, 35, 40, or 50 bases in length. Generally, however, the probes are less than about 1 kilobase in length. Preferably, the probes are single copy probes that hybridize to a unique locus in a haploid chromosome complement. Some exemplary restriction enzymes employed in RFLP mapping are *EcoRI*,
30 *EcoRV*, and *SstI*. As used herein the term "restriction enzyme" includes reference to a composition that recognizes and, alone or in conjunction with another composition, cleaves at a specific nucleotide sequence.

The method of detecting an RFLP comprises the steps of (a) digesting genomic DNA of a plant with a restriction enzyme; (b) hybridizing a nucleic acid probe, under selective hybridization conditions, to a sequence of a polynucleotide of the present of said genomic DNA; (c) detecting therefrom a RFLP. Other methods of differentiating polymorphic (allelic) variants of polynucleotides of the present invention can be had by utilizing molecular marker techniques well known to those of skill in the art including such techniques as: 1) single-stranded conformation analysis (SSCP); 2) denaturing gradient gel electrophoresis (DGGE); 3) Rnase protection assays; 4) allele-specific oligonucleotides (ASOs); 5) the use of proteins which recognize nucleotide mismatches, such as the *E. coli* mutS protein; and 6) allele-specific PCR. Other approaches based on the detection of mismatches between the two complementary DNA strands include clamped denaturing gel electrophoresis (CDGE); heteroduplex analysis (HA); and chemical mismatch cleavage (CMC). Exemplary polymorphic variants are provided in Table I, *supra*. Thus, the present invention further provides a method of genotyping comprising the steps of contacting, under stringent hybridization conditions, a sample suspected of comprising a polynucleotide of the present invention with a nucleic acid probe. Generally, the sample is a plant sample; preferably, a sample suspected of comprising a maize polynucleotide of the present invention (e.g., gene, mRNA). The nucleic acid probe selectively hybridizes, under stringent conditions, to a subsequence of a polynucleotide of the present invention comprising a polymorphic marker. Selective hybridization of the nucleic acid probe to the polymorphic marker nucleic acid sequence yields a hybridization complex. Detection of the hybridization complex indicates the presence of that polymorphic marker in the sample. In preferred embodiments, the nucleic acid probe comprises a polynucleotide of the present invention.

The following examples are offered by way of illustration and not by way of limitation.

EXPERIMENTAL

Mlo Sequences

Eight maize *Mlo* homologue sequences have been identified. The nucleotide sequences (SEQ ID NOS: 1, 3, 5, 7, 9, 11, 13, and 15) and amino acid sequences (SEQ ID NOS: 2, 4, 6, 8, 10, 12, 14, and 16) are provided. DNA sequence analysis was performed according to Sambrook *et al.* (1989) *Mol. Cloning: A Laboratory Manual*, 2nd ed. (Cold Spring Harbor Laboratory Press, Plainview, New York). The maize *Mlo* homologue/orthologue cDNA sequences were identified from mRNA isolated from various maize tissues and used to make cDNAs that are then cloned into vectors, usually pSPORT1. These cDNA libraries are EST sequenced via standard dye-fluorescence labeling and ABI machine electrophoresis and image capture. The *Mlo* homologues were identified by their blast score identity to the barley HvMLO1 published sequence. These maize clones, in particular the longest members of each contig or gene, were obtained and additional sequencing was done on them using oligonucleotide primers designed to internal portions of the cDNA and dye-fluorescence labeling and ABI machine electrophoresis and image capture. The complete edited sequences were assembled and analyzed.

The sequences from maize show sequence similarity to the published barley *Mlo* sequence as provided in Tables 1 and 2. Figure 1 provides a sequence alignment for the maize *Mlo* homologues with the barley *Mlo* sequence designated as HvMlo1. Figure 2 groups the *Mlo* sequences based on relatedness as well as the plant tissue from which it was isolated.

The ZmMLO genes were mapped by RFLP analysis using Southern blots of genomic DNA isolated from F2 and F3 and F4 segregating maize populations. The DNA was isolated using a modified CTAB adapted from the CERES RFLP Lab Manuel based on the Saghai-Mahoof procedure (Saghai-Mahoof *et al.* (1984) *Proc. Natl. Acad. Sci. USA* 81:8014-8018). Genomic DNA was cut with four restriction enzymes *Bam*HI, *Eco*RI, *Eco*RV, and *Hind*III and run (5µg/lane) on 0.8% TAE agarose gels for 800 volt-hours. The gels were Southern blot transferred to Hybond-N membrane (Amersham Life Science), baked and UV-crosslinked. The ZmMLO cDNA inserts were liberated from its vector by cleaving with two restriction enzymes, usually *Sal*I

and *NotI*, and the insert was purified from agarose gels following electrophoresis. The clone was random prime labeled with ^{32}P -dCTP using the RTS (Gibco BRL) labeling kit. The cDNA inserts were used to probe parental screening blots to identify a mapping population with a RFLP polymorphism.

- 5 Once a polymorphism was identified, the inserts were used to probe mapping blots containing DNA from segregating individuals. The map position was determined using MAPMAKER/EXP 3.0 (Lander *et al* (1987) *Genomics* 1:174-181) by scoring 86 segregating progeny as homozygous parent A, as homozygous parent B, or as heterozygous. The map position was assigned to
- 10 an existing core RFLP map of either of the following three populations: ALEB9 (240 individuals) DRAG2 (283 individuals) or MARS (1075 individuals).

Table 3 shows the association of maize *Mlo* homologues and disease related loci and QTLS.

The Trait Utility System for corn (TUSC) system was utilized to generate transposon mutants in the *Mlo* sequences in maize. The combination of transposon mutagenesis via *Mutator* and PCR-based selection of target-specific *Mu* insertions makes up the TUSC system. See, for example, Benson *et al.* (1995) *Plant Cell*. 7:75-84; Mena *et al.* (1996) *Science* 274:1537-1540; U.S. Patent Application No. 08/835,638 and U.S. Patent Application No. 08/262,056; all of which are herein incorporated by reference. Table 4 shows *Mutator* insertion mutants of *ZmMlo* homologues.

Oligonucleotide primers based on *Mlo* maize sequences were designed and paired with *Mu* TIR primer in PCR reactions. The products of the screening process identify individuals in the collection having *Mu* elements inserted into *Mlo* sequences.

The gene-specific primers used for TUSC of *ZmMLO2* are: 19005, 5'-AGTTATCCAAGGCATGCCGGTGGTAAACT-3' (SEQ ID NO:18); and 19007, 5'-AAGTCATCGAGGGAGGCATCACTTACAG-3' (SEQ ID NO:19). For TUSC the mutator-element specific primer used was: 9242, 5'-AGAGAAGCCAACGCCA(AT)CGCCTC(CT)ATTCGTC-3' (SEQ ID NO:20). Seven positive "hits" to *ZmMLO2* were identified. Twenty F2 seeds for each of the hits were planted in the greenhouse and screened as follows. Seeds were planted in trays, containing 2-inch wells for each seed, in Strong-Lite (circleR) Universal Mix potting soil (Universal Mix, Pine Bluff, Arkansas, U.S.A.) and grown in a greenhouse (16 hour day, 20.6-34.8°C, 50% average RH, 560-620 microEinsteins, of light both sun and halogen lamps, averaging 25 heat units per day. Plants were grown for 14-18 days until the V5 stage (ca. 25cm height) and inoculated with spores of *Cochliobolus heterostrophus* (Drechs.) Drechs. Race 0, also known as *Bipolaris maydis* (Southern Leaf Blight) and *Cochliobolus carbonum* R. R Nelson, also known as *Bipolaris zeicola* (Helminthosporium Leaf Spot). For general leaf inoculation, spore suspensions of 4×10^4 per ml of 0.02% Tween-20 were sprayed as an aerosol on the leaves. Approximately 0.5 ml were applied per leaf late in the afternoon. The plants were then immediately covered with a plastic tent and kept at R.T. in order to enhance humidity and spore germination. The plastic tent was removed early in the morning, and the plants were returned to the greenhouse for the duration of the experiment, usually three days. Susceptibility to *Cochliobolus carbonum* was determined by either increased size or number of lesions. Resistance to *Cochliobolus*

heterostrophus was determined by either reduced size or number of lesions. Lesion mimics were also investigated; these mutations form spontaneous lesions in the absence of pathogen attach. Other phenotypes affecting growth and development were also noted.

Example 1: Transformation and Regeneration of Transgenic Plants

Immature maize embryos from greenhouse donor plants are bombarded with a plasmid containing the *ZmMLO1* antisense sequence operably linked to the ubiquitin promoter (Figure 3). This plasmid also contains the selectable marker gene PAT (Wohlleben *et al.* (1988) *Gene* 70:25-37) that confers resistance to the herbicide Bialophos. Transformation is performed as follows. All media recipes are in the Appendix.

Preparation of Target Tissue

The ears are surface sterilized in 30% Chlorox bleach plus 0.5% Micro detergent for 20 minutes, and rinsed two times with sterile water. The immature embryos are excised and placed embryo axis side down (scutellum side up), 25 embryos per plate, on 560Y medium for 4 hours and then aligned within the 2.5-cm target zone in preparation for bombardment.

Preparation of DNA

A plasmid vector comprising the PAT selectable marker and the *ZmMl01* antisense sequence operably linked to a the ubiquitin is made and precipitated onto 1.1 μm (average diameter) tungsten pellets using a CaCl_2 precipitation procedure as follows:

- 100 μl prepared tungsten particles in water
- 10 μl (1 μg) DNA in TrisEDTA buffer (1 μg total)
- 100 μl 2.5 M CaCl_2
- 10 μl 0.1 M spermidine

Each reagent is added sequentially to the tungsten particle suspension, while maintained on the multitube vortexer. The final mixture is sonicated briefly and allowed to incubate under constant vortexing for 10 minutes. After the precipitation period, the tubes are centrifuged briefly, liquid removed, washed with 500 ml 100% ethanol, and centrifuged for 30 seconds. Again the liquid is removed, and 105 μl 100% ethanol is added to the final tungsten particle pellet. For particle gun bombardment, the

tungsten/DNA particles are briefly sonicated and 10 µl spotted onto the center of each macrocarrier and allowed to dry about 2 minutes before bombardment.

Particle Gun Treatment

- 5 The sample plates are bombarded at level #4 in particle gun #HE34-1 or #HE34-2. All samples receive a single shot at 650 PSI, with a total of ten aliquots taken from each tube of prepared particles/DNA.

Subsequent Treatment

- 10 Following bombardment, the embryos are kept on 560Y medium for 2 days, then transferred to 560R selection medium containing 3 mg/liter Bialaphos, and subcultured every 2 weeks. After approximately 10 weeks of selection, selection-resistant callus clones are transferred to 288J medium to initiate plant regeneration. Following somatic embryo maturation (2-4 weeks), well-developed somatic embryos are transferred to
- 15 medium for germination and transferred to the lighted culture room. Approximately 7-10 days later, developing plantlets are transferred to 272V hormone-free medium in tubes for 7-10 days until plantlets are well established. Plants are then transferred to inserts in flats (equivalent to 2.5" pot) containing potting soil and grown for 1 week in a growth chamber, subsequently grown an additional 1-2 weeks in the greenhouse, then transferred to classic
- 20 600 pots (1.6 gallon) and grown to maturity. Plants are monitored and scored for enhanced disease resistance as a result of antisense disruption of *ZmMlo1* function.

APPENDIX**272 V**

Ingredient	Amount	Unit
D-I H ₂ O	950.000	ml
MS Salts (GIBCO 11117-074)	4.300	G
Myo-Inositol	0.100	G

All publications and patent applications mentioned in the specification are indicative of the level of those skilled in the art to which this invention pertains. All publications and patent applications are herein incorporated by reference to the same extent as if each individual publication or patent application was specifically and
5 individually indicated to be incorporated by reference.

Although the foregoing invention has been described in some detail by way of illustration and example for purposes of clarity of understanding, it will be obvious that certain changes and modifications may be practiced within the scope of the appended claims

INDICATIONS RELATING TO DEPOSITED MICROORGANISM
OR OTHER BIOLOGICAL MATERIAL

(PCT Rule 13bis)

A. The indications made below relate to the deposited microorganism or other biological material referred to in the description on page 5, lines 11-20	
B. IDENTIFICATION OF DEPOSIT Further deposits are identified on an additional sheet <input type="checkbox"/>	
Name of depository institution American Type Culture Collection	
Address of depository institution (including postal code and country) Manassa, Virginia USA	
Date of deposit	Accession Numbers 98725-98729
C. ADDITIONAL INDICATIONS (leave blank if not applicable) This information is continued on an additional sheet <input type="checkbox"/>	
D. DESIGNATED STATES FOR WHICH INDICATIONS ARE MADE (if the indicators are not for all designated States)	
E. SEPARATE FURNISHING OF INDICATIONS (leave blank if not applicable)	
The indications listed below will be submitted to the International Bureau later (specify the general nature of the indications e.g., "Accession Number of Deposit") Date of Deposit	

For receiving Office use only
<input checked="" type="checkbox"/> This sheet was received with the international application
Authorized officer 

For International Bureau use only

WHAT IS CLAIMED IS:

1. A method for creating or enhancing disease resistance in a plant, said method comprising modulating the expression of an *Mlo* nucleotide sequence wherein said nucleotide sequence is selected from the group consisting of:

- (a) a nucleotide sequence encoding a maize *Mlo* gene;
- (b) a nucleotide sequence encoding at least one of the maize MLO amino acid sequences selected from the group consisting of the sequences set forth in SEQ ID NOS: 2, 4, 6, 8, 10, 12, 14, and 16;
- (c) a nucleotide sequence comprising at least one of the nucleotide sequences set forth in SEQ ID NOS: 1, 3, 5, 7, 9, 11, 13, and 15;
- (d) a nucleotide sequence selected from the group consisting of sequences deposited in the American Type Culture Collection as Accession Nos. 98725, 98726, 98727, 98728, and 98729;
- (e) a nucleotide sequence that encodes an antisense sequence corresponding to a sequence of a), b), c) or d);
- (f) a nucleotide sequence which hybridizes under stringent conditions to one of the nucleotide sequences set forth in a), b), c), d) or e).

2. The method of claim 1, wherein said modulation comprises decreasing the expression of the *Mlo* sequence.

3. The method of claim 1, wherein said plant is a monocot.

4. The method of claim 3, wherein said monocot is maize.

5. A modified plant having altered levels of an MLO protein wherein said plant has stably incorporated into its genome a DNA construct, wherein said DNA construct comprises a nucleotide sequence operably linked

to a promoter capable of regulating transcription of said sequence in said plant, wherein said nucleotide sequence is selected from the group consisting of:

- (a) a nucleotide sequence encoding a maize *Mlo* gene;
- (b) a nucleotide sequence encoding at least one of the maize MLO amino acid sequences selected from the group consisting of the sequences set forth in SEQ ID NOS: 2, 4, 6, 8, 10, 12, 14, and 16;
- (c) a nucleotide sequence comprising at least one of the nucleotide sequences set forth in SEQ ID NOS: 1, 3, 5, 7, 9, 11, 13, and 15;
- (d) a nucleotide sequence selected from the group consisting of sequences deposited in the American Type Culture Collection as Accession Nos. 98725, 98726, 98727, 98728, and 98729;
- (e) a nucleotide sequence that encodes an antisense sequence corresponding to a sequence of a), b), c) or d);
- (f) a nucleotide sequence which hybridizes under stringent conditions to one of the nucleotide sequences set forth in a), b), c), d) or e).

6. The modified plant of claim 5, wherein said plant exhibits a decrease in the expression of a *Mlo* gene.

7. The modified plant of claim 5, wherein said plant is a monocot.

8. The modified plant of claim 7, wherein said monocot is maize.

9. The maize plant of claim 8, wherein said plant has decreased levels of the *Mlo* protein.

10. The maize plant of claim 8, wherein said maize plant comprises an insertion sequence in at least one maize *Mlo* gene.

11. Seed of the plant of any one of claims 5, 6, 7, 8, 9, and 10.

12. An isolated MLO protein, wherein said protein comprises an amino acid sequence selected from the group consisting of the MLO amino acid sequences set forth in SEQ ID NOS: 2, 4, 6, 8, 10, 12, 14, and 16.

13. An isolated nucleotide sequence said sequence selected from the group consisting of:

- (a) a nucleotide sequence encoding a maize *Mlo* gene;
- (b) a nucleotide sequence encoding at least one of the maize MLO amino acid sequences selected from the group consisting of the sequences set forth in SEQ ID NOS: 2, 4, 6, 8, 10, 12, 14, and 16;
- (c) a nucleotide sequence comprising at least one of the nucleotide sequences set forth in SEQ ID NOS: 1, 3, 5, 7, 9, 11, 13, and 15;
- (d) a nucleotide sequence selected from the group consisting of sequences deposited in the American Type Culture Collection as Accession Nos. 98725, 98726, 98727, 98728, and 98729;
- (e) a nucleotide sequence that encodes an antisense sequence corresponding to a sequence of a), b), c) or d);
- (f) a nucleotide sequence which hybridizes under stringent conditions to one of the nucleotide sequences set forth in a), b), c), d) or e).

14. A modified plant cell having an altered level of an MLO protein wherein said plant cell has stably incorporated into its genome a DNA construct, wherein said DNA construct comprises a nucleotide sequence operably linked to a promoter capable of regulating transcription of said sequence in said plant cell, wherein said nucleotide sequence is selected from the group consisting of:

- (a) a nucleotide sequence encoding a maize *Mlo* gene;
- (b) a nucleotide sequence encoding at least one of the maize MLO amino acid sequences selected from the group consisting of the sequences set forth in SEQ ID NOS: 2, 4, 6, 8, 10, 12, 14, and 16;
- (c) a nucleotide sequence comprising at least one of the nucleotide sequences set forth in SEQ ID NOS: 1, 3, 5, 7, 9, 11, 13, and 15;

- (d) a nucleotide sequence selected from the group consisting of sequences deposited in the American Type Culture Collection as Accession Nos. 98725, 98726, 98727, 98728, and 98729;
- (e) a nucleotide sequence that encodes an antisense sequence corresponding to a sequence of a), b), c) or d);
- (f) a nucleotide sequence which hybridizes under stringent conditions to one of the nucleotide sequences set forth in a), b), c), d) or e).

15. The modified plant cell of claim 14, wherein said cell exhibits a decrease in the expression of an *Mlo* gene.

16. The modified plant cell of claim 14, wherein said cell is from a monocot.

17. The modified plant cell of claim 16, wherein said monocot is maize.

INTERNATIONAL SEARCH REPORT

Int. onal Application No
PCT/US 99/15255

A. CLASSIFICATION OF SUBJECT MATTER

IPC 7 C07K14/415 C12N15/82 A01H5/00

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

IPC 7 C07K C12N A01H

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	WO 98 04586 A (INNES JOHN CENTRE INNOV LTD ;PANSTRUGA RALPH (GB); BUESCHGES RAINE) 5 February 1998 (1998-02-05) the whole document	1-11, 13-17
X	DATABASE EMBL Online! EMBL AC/ID AA660856, 14 November 1997 (1997-11-14) COVITZ P A ET AL.: "Expressed sequence tags from a root hair-enriched Medicago trunculata cDNA library" XP002119426 abstract	13

☒ Further documents are listed in the continuation of box C.

☒ Patent family members are listed in annex.

* Special categories of cited documents:

- "A" document defining the general state of the art which is not considered to be of particular relevance
- "E" earlier document but published on or after the international filing date
- "L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- "O" document referring to an oral disclosure, use, exhibition or other means
- "P" document published prior to the international filing date but later than the priority date claimed

- "T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
- "X" document of particular relevance: the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
- "Y" document of particular relevance: the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.
- "&" document member of the same patent family

Date of the actual completion of the international search

19 October 1999

Date of mailing of the international search report

03/11/1999
